Community Advisory Group Meeting
April 4, 2016
Background

Over recent years we have learned a lot from the Community Advisory Group and from residents of Ambler regarding concerns and questions about the implications of living nearby and being involved in the asbestos manufacturing industry.

We would now like to partner with you to learn more about these implications.
We are preparing to launch a new study set in Ambler and the greater Ambler area.

Our goal is to understand the link between work, community and environmental exposure to asbestos and the risk for developing mesothelioma among residents of the Ambler area.
We aim to conduct a case-control study where we compare individuals who developed mesothelioma (cases) to individuals who lived in Ambler but do not have mesothelioma (controls).

We will look back over time to determine and compare how much exposure case subjects experienced and how much exposure control subjects experienced.
Case participants

Participants who are case subjects in the study will be those who:

- Have a diagnosis of mesothelioma
- Lived in the greater Ambler area at the time of diagnosis
- Have lived in the greater Ambler area for at least 5 years at the time of diagnosis
Participants who are control subjects in the study will be those who:

- Do not have a diagnosis of mesothelioma
- Are the same age and gender as a matched case participant at the time of the case participant’s diagnosis
- Had lived in the greater Ambler area for at least 5 years prior to the matched case participant’s diagnosis
What we are asking you?

• As a concerned member of the community:
  How can we raise awareness about the study?

• As a person who qualifies as a case subject or as a control subject?

We would ask you to complete a survey, either in person or over the phone, with a member of our research staff. We would ask you questions about where you (or your loved one) have lived, for how long you (or your loved one) lived there, what jobs you (or your loved one) have had, your (or your loved one’s) medical history, and any family history of mesothelioma. We will use these surveys to compare case subjects to control subjects, which will help us understand links between asbestos exposure and development of mesothelioma.
Can we answer any questions?

We would appreciate your input:
Can you help us understand the best ways to include members of the community in this process?
To provide input or to participate in a survey, please contact us:
