During menopause, many women subjectively report a decrease in their cognitive functioning including difficulty with concentration, memory and attention. Women who undergo acute surgically induced menopause through oophorectomy or hysterectomy are at a greater risk for these symptoms.

Our study seeks to determine the effectiveness of a stimulant drug called Vyvanse® on the cognitive functioning in these women. The research study involves functional brain imaging, cognitive tests and blood draws.

You may qualify for study participation if:

- You underwent surgically induced menopause within the past 10 years
- You are experiencing cognitive difficulties
- You are otherwise medically healthy

Participants will be compensated for their time.
